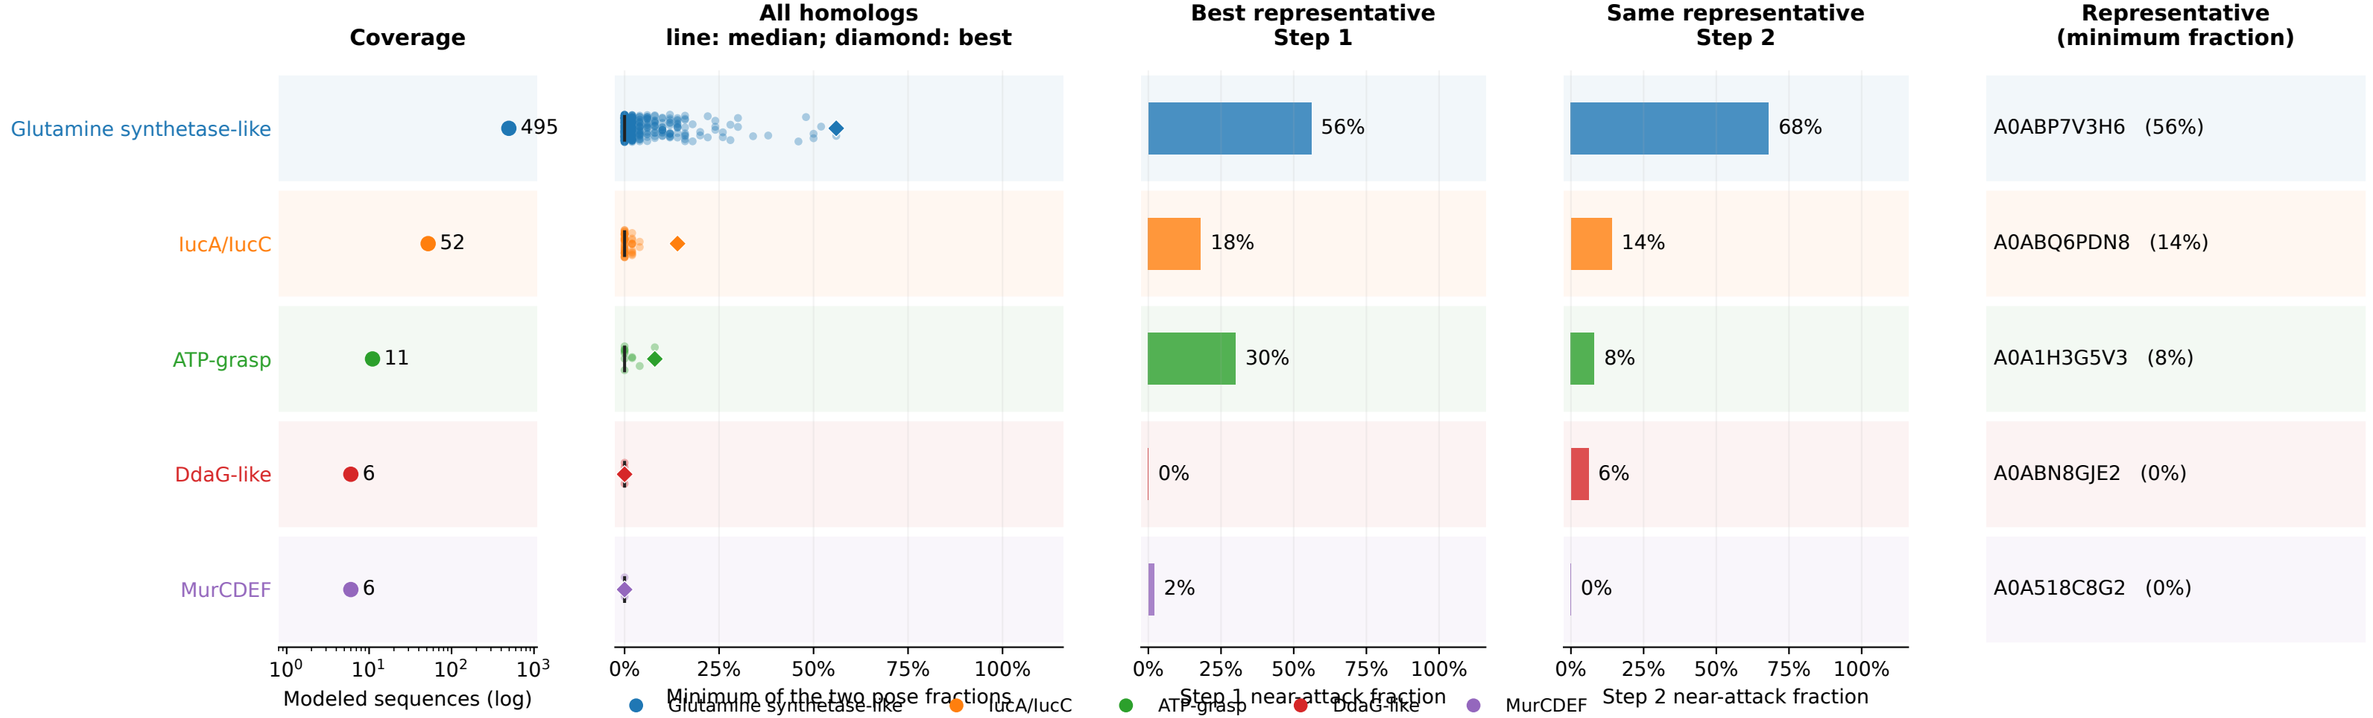
# Glutarate + cadaverine: broad protein families and sampling coverage

Both stages are evaluated together. Large groups expose more candidates to selection; coverage and full distributions are shown.



Structural heuristic: min(step 1 near-attack fraction, step 2 near-attack fraction). Best representatives maximize this value; tied scores are not distinct activity ranks.
Family labels come from reference-enzyme UniProt/Pfam annotations transferred through the saved homolog mapping. This is not a phylogenetic orthology analysis.
